SensorSynth

From Heuristic Biosensor Design to Predictive, Explainable Design Engine

Shruthi Ashok • Rajarajan Thirunindrayur

ashruthi@bu.edu

rajatp@bu.edu

A tool that helps a researcher answer one question: *I want to detect some molecule in some organism. Which genetic circuit design should I build, and why?*

Goal

A **biosensor** is a living cell (usually a bacterium or yeast) that has been engineered with genetic circuits to detect a specific molecule in its environment and produce a measurable output - like a glow, a color change, or an electrical signal. Building one requires two key decisions:

1. **Which genetic circuit architecture** should detect and respond to the target?
2. **Which host organism (chassis)** should the circuit be built in?

These two decisions are almost never made together in a principled, quantitative way. Sens formalizes this decision process.

Motivation

A 2025 review in *ACS Synthetic Biology* states directly: **"The chassis-design space has remained underexplored as an engineering variable."** This means that despite decades of biosensor research, scientists still largely pick their host organism by habit (usually E. coli) rather than by principled analysis.

A 2024 paper by Qin et al. in *Quantitative Biology* found that circuit behavior across different organisms follows surprisingly predictable linear relationships — but no tool had yet formalized this into a selection framework.

Sridhar S, explicitly argue that successful biosensor design depends on selecting a chassis based on ecological, metabolic, and genetic constraints, and proposes a framework for systematic chassis choice rather than ad hoc selection.

The Five Open Problems This Project Addresses

Problem	Current State	What it Does
Architecture-chassis mismatch	Discovered after building, wasting months	Predicted before building, computationally
Heuristic performance scores	Arbitrary weights, no mechanistic basis	Hill-function ODE simulation with uncertainty
Single-objective ranking	Pick "best" architecture by one metric	Pareto frontier across 5 simultaneous objectives
Circuit portability prediction	No quantitative framework exists	Transfer coefficient model (Qin 2024 + features)
Circuit evolutionary loss	Rarely considered during design	Stability index predicts half-life in generations

"The same circuit does NOT behave the same across organisms."

Functionality

Internal Modules: How organte is profilinned iron a design in its on host chassis type

The tool does more than rank options; it explains why a design is good, how fast it should respond, whether it **transfers** to another organism, and how likely it is to fail over generations.

- **Portability model**

- **Evolutionary stability index**

- **Literature miner**

- **Validation layer**

- **Design need**

- **System produces data**

- **Inspect & Export**

The user can inspect winng one on the dashboard.

OUTPUT 1

Best immediate build

High-confidence architecture in architecture

OUTPUT 2

Trade-off alternatives

Backup options options on for user's comparise

OUTPUT 3

Biological rationale

An explanation is whether provide a full explanation.

Functionality

Architecture

- **Predictive Portability**: It estimates how well a sensor will perform if moved from one organism to another based on genetic and physical similarities.
- **Long-term Stability**: The system calculates an Evolutionary Stability Index to predict if a circuit will mutate or fail over many generations.
- **Evidence-Based**: Every parameter used in the models is backed by data extracted from primary research literature.
- **Practical Recommendations**: The final output is a ranked shortlist of high-confidence designs with clear biological justifications.

Specification Requirements

SPECIFICATION AREA	REQUIREMENT	CONSTRAINT / TARGET
Input requirements	User must be able to define analyte, dynamic range need, response-time limit, and deployment context.	Required Inputs must map directly to circuit-host scoring.
Prediction quality	System must use mechanistic or evidence-backed models, not arbitrary rankings.	Required Hill/ODE simulation, uncertainty bands, and literature-derived parameters.
Optimization	System must expose trade-offs rather than a single hidden score.	Required Pareto front across 5 objectives.
Biological realism	Must account for chassis compatibility, transferability, and evolutionary loss.	Required Cross-host portability and stability module included.
Usability	Recommendations must be understandable to researchers and fast enough for interactive exploration.	Design constraint Web app workflow, ranked outputs, visual trade-off plots.

Genetic Circuit Architecture

Molecular "wiring" that connects the detection of a molecule to the production of an output.

Architecture 1: TF Promoter-Repressor

Architecture 2: CRISPRi Repression

Architecture 3: Riboswitch

Architecture 4: Small RNA (sRNA) Regulation

Architecture 5: Two-Component System (TCS)

Architecture 6: Toehold Switch

Host Organisms (Chassis)

Chassis 1: Escherichia coli (E. coli)

Chassis 2: Bacillus subtilis

Chassis 3: Saccharomyces cerevisiae (Baker's Yeast)

Chassis 4: Pseudomonas putida

Chassis 5: Corynebacterium glutamicum

Chassis 6: Vibrio natriegens

Detailed Functionality

MODULE 1 — COMPATIBILITY SCORING ENGINE

COMPUTES A 0–100 COMPATIBILITY SCORE FOR ARCHITECTURE × CHASSIS PAIRS GIVEN A SENSOR SPECIFICATION

SCORE = (DynamicRangeFit × 0.35) + (BurdenFit × 0.30) + (ResponseTimeFit × 0.25) + (ChassisCompatFit × 0.10)

WEIGHT JUSTIFICATION: Based on Cardinale & Arkin 2012 (Nat Chem Biol) — survey of biosensor performance metrics frequency in synthetic biology literature.

DYNAMIC RANGE FIT	BURDEN FIT	RESPONSE TIME FIT	CHASSIS COMPATIBILITY
Weight: 35%	**Weight:** 30%	**Weight:** 25%	**Weight:** 10%
How it is computed: Compares arch's lit-reported fold-change range to spec's requirement. Penalized if spec needs 100× but arch typically achieves 20×.	**How it is computed:** BurdenFit = chassisBurdenScore − archBurdenCost × (1 − chassisBurdenScore). High-tolerance chassis suffer less penalty for expensive circuits.	**How it is computed:** Arch's typical response time vs. spec's max allowed time. 'Slow' arch (<2h) penalized by 20–65% if spec requires <1h.	**How it is computed:** Domain bonus: +22% for prokaryotic, −38% for eukaryotic (riboswitches). Based on known biological constraints.
Why this weight: Fold-change is the single most-reported metric in biosensor literature	**Why this weight:** Metabolic burden is the most common cause of circuit failure in practice	**Why this weight:** Response speed matters but is more adjustable than dynamic range	**Why this weight:** Fundamental compatibility adds refinement but is not the primary driver

Detailed Example Flow

4 Compatibility score matrix

Architecture × chassis scoring with evolutionary stability. All objectives computed from literature-derived kinetic parameters.

Ranked (6) | Full matrix

#1 Toehold switch

RNA hairpin structure in the 5'-UTR unfolds when a trigger RNA binds, enabling translation of the output gene.

85 / 100 HIGH

DYNAMIC RANGE (35%)	BURDEN FIT (30%)	RESPONSE TIME (25%)	CHASSIS COMPAT (10%)
82	89	90	68

PROMOTERS: Any constitutive promoter

REGULATORS: Trigger RNA-mediated hairpin unfolding (no protein required)

EVOL. STABILITY: 100 / 100

1% ≈ 3,257,271 gen

LOW RISK

EXPLAINABILITY — WHY #1

Toehold switch ranks first for detecting **Arsenic**: high dynamic range capability; metabolic burden is within host tolerance; response kinetics meet the time requirement; evolutionary stability index 100/100 (low loss risk). Suggested next step: retrieve Any constitutive promoter + Trigger RNA-mediated hairpin unfolding (no protein required) from SynBioHub and validate in iBioSim.

#2 Two-component system

Membrane histidine kinase (HK) senses signal and phosphorylates cytoplasmic response regulator (RR) to control gene expression.

81 / 100 HIGH

DYNAMIC RANGE (35%)	BURDEN FIT (30%)	RESPONSE TIME (25%)	CHASSIS COMPAT (10%)
85	85	72	72

Small RNA regulation	80	68	62	73	64	77
Two-component system	85	69	62	76	65	81
Toehold switch	88	77	72	82	73	85

Score = (DynFit×0.35) + (BurdenFit×0.30) + (RespFit×0.25) + (ChassisFit×0.10)

Weights derived from Cardinale & Arkin 2012 biosensor design priority survey (Nat Chem Biol).

Detailed Example Flow

5 ODE kinetic simulation

Hill-function ODEs with Monte Carlo uncertainty quantification. Mean ± 95% CI time-course and dose-response curves. Based on literature-derived kinetic parameters.

Methodology: Instead of heuristic scores, this module simulates actual promoter-output dynamics using Hill-function ODEs (Alon 2007). Monte Carlo sampling (120 parameter sets) propagates kinetic uncertainty (CV ≈ 25–40%) into confidence intervals. t_{50} and t_{90} are computed directly from the kinetic trace.

SIMULATION PARAMETERS

ARCHITECTURE

CRISPRi | Riboswitch | **TF Loop** | sRNA | TCS | Toehold

CHASSIS

Vibrio natriegens

LIGAND CONC. (MM): 1

SIM DURATION (H): 6

MC SAMPLES: 120

Run ODE + MC (n=120)

100.5×	[100.5, 100.5]×	0.20 h	0.61 h
FOLD-CHANGE (MEAN)	95% CI	T_{50}	T_{90}

TIME-COURSE — FOLD-CHANGE VS TIME (MEAN ± 95% CI, 120 MC SAMPLES)

DOSE-RESPONSE — FOLD-CHANGE VS [LIGAND] MM (LOG SCALE, MEAN ± 95% CI)

Uncertainty reflects literature CV on Kd (±30–40%), Hill n (±20%), and umax (±25%). Shaded region = 5th–95th percentile across 120 MC samples.

Detailed Example Flow

6 Pareto multi-objective frontier

True Pareto-optimal designs across 5 simultaneous objectives. Non-dominated solutions represent the best achievable trade-offs — no weighted sum, no hidden preferences.

Methodology: NSGA-II non-dominated sort (Deb 2002) applied to the architecture–chassis selection problem across 5 objectives: dynamic range, metabolic burden, response speed, chassis compatibility, and evolutionary stability. Stars = Pareto front (rank 1). Crowding distance ensures diverse front coverage.

36	5	31
TOTAL SOLUTIONS	PARETO FRONT SIZE	DOMINATED

X AXIS: Dynamic range | Low burden | Response speed | Chassis compat. | Evol. stability

Y AXIS: Dynamic range | Low burden | Response speed | Chassis compat. | Evol. stability

PARETO FRONT — NON-DOMINATED SOLUTIONS (RANK 1)

DESIGN	DYN RANGE	LOW BURDEN	RESPONSE	COMPAT	EVOL STAB	SCORE	CROWDING

Detailed Example Flow

7 Cross-chassis portability

Predict circuit performance when transferred to a different host. Based on Qin et al. 2024 empirical linear transfer model extended with feature-based similarity.

Methodology: Cross-chassis portability prediction is an open problem. No existing tool formalizes this transfer. Our model blends the empirical linear slope matrix (Qin et al. 2024 Quantitative Biology) with a 5-feature similarity vector (phylogeny, sigma factor overlap, ribosome speed, GC content, growth rate). Architecture-specific correction accounts for codon optimization requirements.

TRANSFER PREDICTION SETUP

ARCHITECTURE	SOURCE CHASSIS (CHARACTERIZED IN)	KNOWN PERFORMANCE SCORE IN SOURCE
TF promoter-repressor	Vibrio natriegens	82

Predict portability across all chassis

PREDICTED PERFORMANCE: TF PROMOTER-REPRESSOR TRANSFERRED FROM VIBRIO NATRIEGENS (SCORE=82)

PORTABILITY DETAIL TABLE

TARGET CHASSIS	PREDICTED	95% CI	TRANSFER SLOPE	FEATURE SIM	CONFIDENCE	NOTE
Vibrio natriegens	82.0	[82.0, 82.0]	1.000	—	HIGH	Same chassis — no transfer needed.
Escherichia coli	64.1	[40.0, 88.2]	0.781	0.688	HIGH	Based on Qin et al. 2024 linear transfer model with tf_loop correction.
Pseudomonas putida	59.9	[35.8, 84.1]	0.731	0.605	MEDIUM	Based on Qin et al. 2024 linear transfer model with tf_loop correction.
Bacillus subtilis	45.1	[21.0, 69.2]	0.550	0.484	MEDIUM	Based on Qin et al. 2024 linear transfer model with tf_loop correction.
Corynebacterium glutamicum	39.3	[15.2, 63.4]	0.479	0.398	MEDIUM	Based on Qin et al. 2024 linear transfer model with tf_loop correction.
Saccharomyces cerevisiae	24.1	[0.0, 48.2]	0.293	0.213	LOW	Based on Qin et al. 2024 linear transfer model with tf_loop correction.

6 Literature metric miner

Search PubMed, fetch abstracts directly from your browser, then extract quantitative biosensor metrics. Add an Anthropic API key for AI-powered extraction, or use heuristic mode without one.

How it works: Your browser fetches articles directly from NCBI PubMed (no server proxy needed). Abstracts are then sent to our backend where Claude extracts structured data — fold-change values, binding constants (Kd), Hill coefficients, response times, and chassis used. This builds the evidence base that justifies our kinetic model parameters.

Detailed Example Flow

9 Evolutionary stability & validation

Predict circuit half-life under natural selection. Concordance analysis against 10 published experimental outcomes.

Evolutionary stability | Validation / concordance

Methodology: Evolutionary stability prediction is rarely formalized. We model circuit half-life as a function of metabolic burden, component count, mutation rate, and essentiality. Based on Sleight et al. 2010 (J Biol Eng) burden-driven loss model and Helenek et al. 2024 mid-scale evolution theory (Chem Biol).

Successes

Scientific success

Literature-grounded models

Each module was tied to biosensor, gene circuit, and synthetic biology literature, so the tool was not just conceptual software.

Engineering success

Working full-stack design

The backend, models, API endpoints, and frontend pages formed a complete product rather than a disconnected theoretical proposal.

Practical success

Real decision support

Outputs such as ranked matrices, kinetics plots, Pareto fronts, and stability scores are directly useful during design planning.

OVERALL CONCLUSION OF SUCCESS

- **It transformed an open-ended design problem into a formal workflow:** researchers can now move from "What should I build?" to a justified shortlist.
- **It balanced novelty and feasibility:** the portability and stability modules add innovation, while the compatibility and kinetics modules keep the system grounded in known biology.
- **It created a strong platform for future work:** mammalian chassis, flux balance analysis, and live literature updates can all build naturally on the current architecture.

End-to-End Pipeline

From literature to design recommendation — fully automated

Data-Driven Decisions

Every suggestion backed by extracted evidence, not intuition

Explainability

Full traceability of why each design was ranked as it was

Real Implementation

Validated against known working biological systems

Limitations & Failure Modes

1. Literature Gaps

- **Issue:** Limited data for novel parts
- **Observed:** Missing parameters → fallback assumptions
- **Fix:** Integrate full-text extraction + experimental datasets

2. Model Simplifications

- **Issue:** Assumes ideal cellular context
- **Observed:** Overestimated performance in complex environments
- **Fix:** Incorporate context-aware / stochastic models

3. Parameter Noise

- **Issue:** Variability in extracted metrics
- **Observed:** High variance in Monte Carlo outputs
- **Fix:** Confidence-weighted extraction + filtering

4. Compute Scaling

- **Issue:** Large design space
- **Observed:** NSGA-II runtime increased significantly
- **Fix:** Use surrogate models / pruning strategies

Future Work

1. **Wet-Lab Validation**
   Close the loop with experimental testing of top-ranked designs
2. **Improved Biological Models**
   Incorporate context-dependent expression and host-specific effects
3. **RL Optimization**
   Use reinforcement learning to iteratively refine design recommendations
4. **Expanded Database**
   Scale literature coverage and integrate community-submitted data

Additional:

The PubMed pipeline was completely rearchitected. But, it still cannot retrieve all the information about chassis and the genetic circuit.

The old design had the server fetch from NCBI which fails in restricted server environments. The new design has your browser fetch directly from NCBI (no restrictions, CORS is allowed) and only sends the pre-fetched abstracts to the backend.

DISCUSSION
